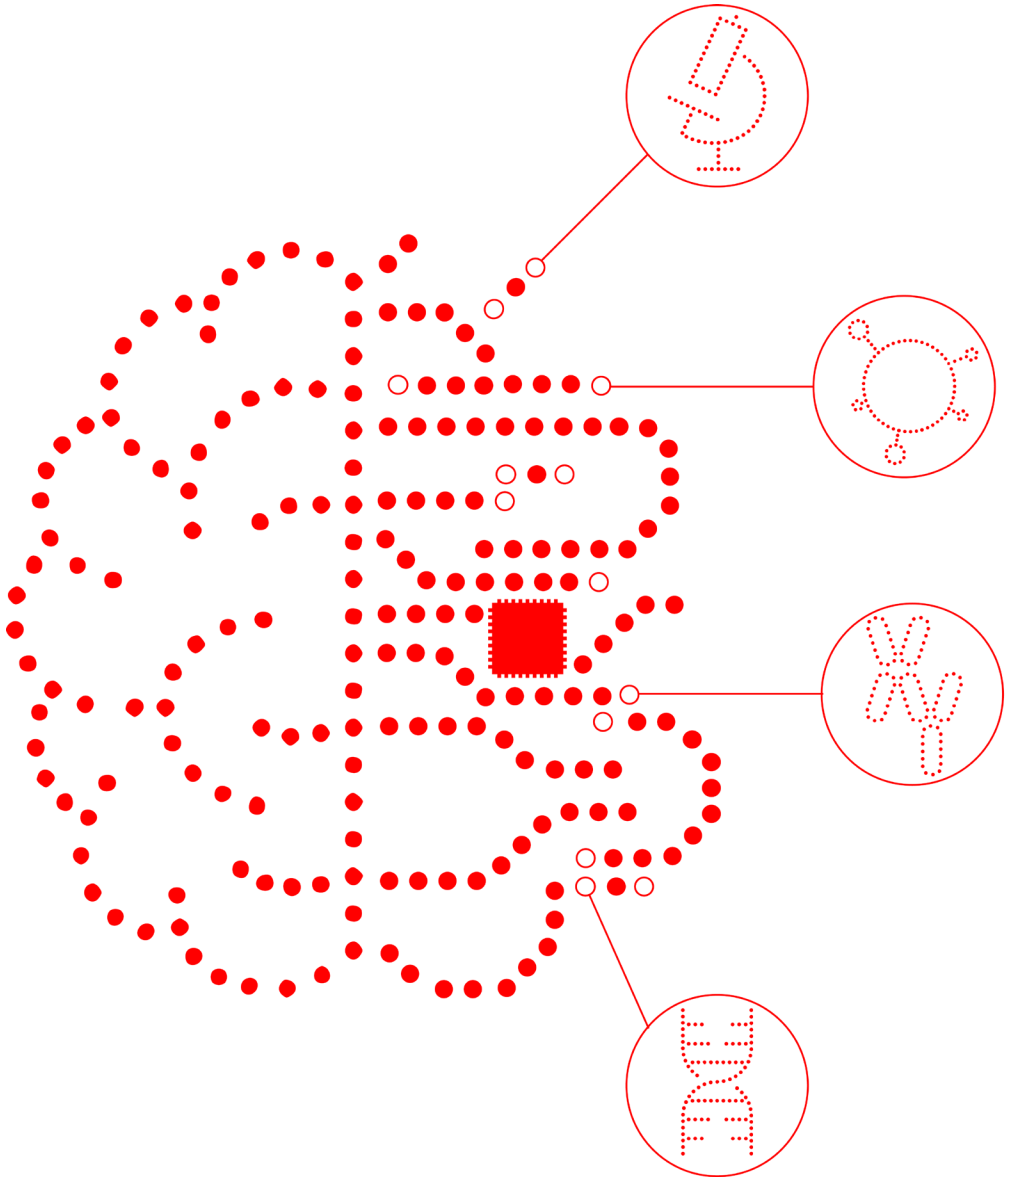
Current diagnostic tools for leukemias

Key diagnostic tools include cytomorphology, cytogenetics, immunophenotyping, histology, FISH, and molecular genetics



FISH, fluorescence *in situ* hybridization.

Diagnostic tools in leukemias 2025+

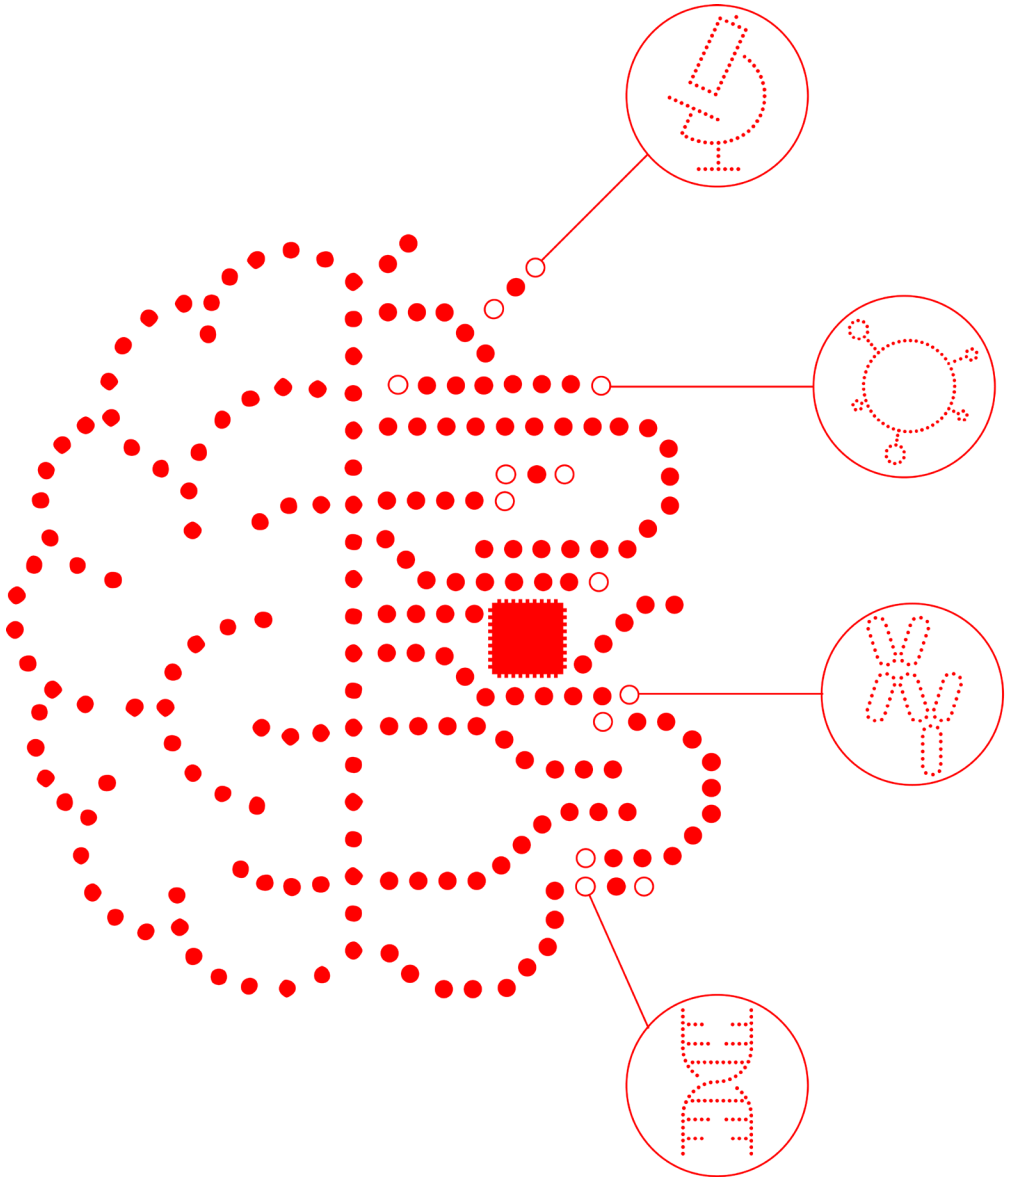
Next steps to advance diagnostics?
AI – large language models

AI and LLMs hold significant potential to improve healthcare, but they must be used in compliance with relevant regulations



AI, artificial intelligence; LLM, large language model.

Current and proposed regulations for the use of AI

FDA 2021 action plan outlines five goals:[1]

- Tailored regulatory framework
- Good machine learning practices
- Patient-centered approach with increased transparency
- Reducing algorithm bias
- Real-world performance

7 pages

EU 2024 AI Act includes:[3]

- Enhanced oversight
- Explainability
- Data integrity
- Human in the loop
- International standards

458 pages

WHO regulatory considerations 2023 on AI suggest:[2]

- Documentation and transparency
- Risk management and AI systems development lifecycle approaches
- Intended use and analytical and clinical validation
- Data quality
- Privacy and data protection

80 pages

Standardising acute myeloid leukaemia classification systems: a perspective from a panel of international experts (Shallis RM *et al. Lancet Haematol* 2023; 10 (9): E767–E776)

Standardising acute myeloid leukaemia classification systems: a perspective from a panel of international experts

The existence of two acute myeloid leukaemia classification systems—one put forth by WHO and one by the International Consensus Classification in 2022—is concerning. Although both systems appropriately move towards genomic disease definitions and reduced emphasis on blast enumeration, there are consequential disagreements between the two systems on what constitutes a diagnosis of acute myeloid leukaemia. This fundamental problem threatens the ability of heath-care providers to diagnose acute myeloid leukaemia, communicate with patients and other health-care providers, and deliver appropriate and consistent management strategies for patients with the condition. Clinical trial eligibility, standardised response assessments, and eventual drug development and regulatory pathways might also be negatively affected by the discrepancies. In this Viewpoint, we review the merits and limitations of both classification systems and illustrate how the coexistence, as well as application of both systems is an undue challenge to patients, clinicians, hematopathologists, sponsors of research, and regulators. Lastly, we emphasise the urgency and propose a roadmap, by which the two divergent classification systems can be harmonised.

Introduction

Our understanding of the genetic landscape of acute myeloid leukaemia and how its underlying pathobiology links to clinical phenotype and patient outcomes has greatly improved over the last 20 years. Albeit slowly, therapeutic successes have followed with multiple new drugs approved since 2017. Concurrently, there has been an important and continued effort to integrate genetic data into day-to-day clinical decision making, to develop a personalised management approach for acute myeloid leukaemia treatment. However, the rapidly increasing quantity and complexity of genetic, pathological, and clinical variables to be integrated into optimal therapy and risk-based decision making is complicating an already multilayered and rapidly evolving management schema. A new challenge to the creation of such a data-driven consensus approach to personalised acute myeloid leukaemia treatment is the emerging disagreement among experts about what should constitute a diagnosis of the condition (ie, the absence of a shared consensus regarding the classification criteria for acute myeloid leukaemia). In 2022, WHO[1] and the International Consensus Classification (ICC)[2] offered distinct frameworks, through which myeloid neoplasms can be classified and approached diagnostically. Furthermore, the European LeukemiaNet (ELN),[3] which largely aligns with the ICC, has provided updated risk stratification and response criteria for acute myeloid leukaemia that might further influence clinical management and treatment decisions. However, the discordance between these well intended systems introduces great variability in diagnostic terminology, acute myeloid leukaemia management, patients' clinical trial eligibility, and clinical outcome assessments. Eventually, this issue might delay clinical drug development, lead to heterogeneity in populations enrolled onto clinical trials, and affect the regulatory pathway of emerging drugs. In this Viewpoint, we review the potential impetus for the development of the contemporary acute myeloid leukaemia classification systems, their inherent limitations (particularly as they relate to risk stratification for routine clinical practice and clinical drug development), and how divergent classification systems complicate diagnosis and management decisions, and confuse clinicians and patients. We offer an opinion on how to move forward in patient care and clinical research.

Regressing myeloblast thresholds

Classification systems for myeloid neoplasms have evolved to rationally incorporate genetics and biology. Under the previous, widely used French–American–British classification from 1976, patients with myelodysplastic syndromes and 20–29% blasts were included in a subcategory of myelodysplastic syndromes, known as refractory anaemia with excess blasts in transformation.[4] The subsequent recognition that patients with 20–29% blasts and those with at least 30% blasts had similar clinical outcomes prompted WHO in 2001, to eliminate refractory anaemia with excess blasts in transformation as a myelodysplastic syndromes category, and to reduce the arbitrary acute myeloid leukaemia-defining marrow or peripheral blood blast threshold to at least 20%. This change did not affect the core-binding factor (CBF) acute myeloid leukaemia and acute promyelocytic leukaemia, which continued to be defined based on the identification of an acute myeloid leukaemia-defining genetic abnormality, irrespective of the blast count.[5] The 20% marrow or blood blast threshold, at which morphologically defined acute myeloid leukaemia is diagnosed, has been retained in both the

Summarize the comparison of WHO and ICC and future steps in 8 bullet points

- The WHO and ICC have divergent classification systems for acute myeloid leukaemia (AML), with differences in diagnostic criteria and blast count requirements for AML diagnosis.
- WHO's 2022 classification emphasizes therapy-associated categories for population health studies and introduces "myeloid neoplasms post-cytotoxic therapy" to replace "therapy-related myeloid neoplasm."
- ICC's 2022 classification does not use medical history to define secondary AML and sets a 10% mutant TP53 variant allele frequency (VAF) cutoff for defining AML with mutated TP53 and adverse risk disease.
- WHO considers previous PARP inhibitor exposure as myeloid neoplasms post cytotoxic therapy, while ICC does not specifically account for it.
- Discrepancies between WHO and ICC classifications could impact clinical trial eligibility, standardised response assessments, and drug development pathways.
- ICC-proposed and ELN-adopted myelodysplastic syndromes categories aim to establish consistency and expand eligibility for future trials and therapies.
- The coexistence of WHO and ICC systems poses challenges to patients, clinicians, hematopathologists, research sponsors, and regulators due to conflicting diagnostic and management strategies.
- A roadmap is proposed for harmonizing the two classification systems to ensure consistent diagnosis, treatment, and clinical trial eligibility for AML.

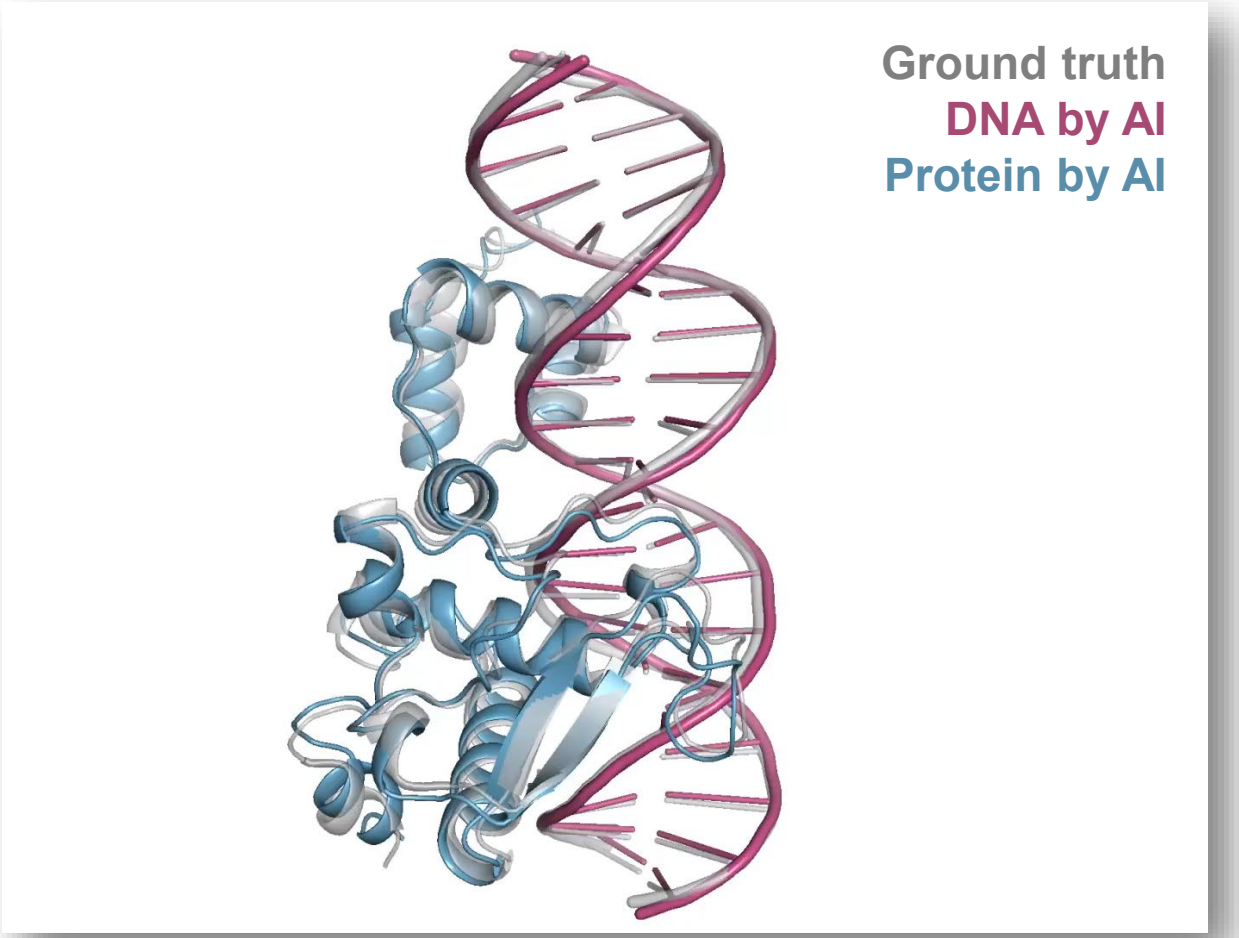
AI for drug development



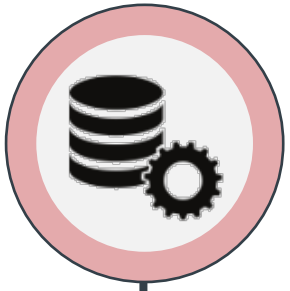
7R6R – DNA-binding protein: AlphaFold 3's prediction for a molecular complex featuring a protein bound to a double helix of DNA is a near-perfect match to the true molecular structure discovered through painstaking experiments.

AI, artificial intelligence.

Google. AlphaFold 3 predicts the structure and interactions of all of life's molecules. Available at: https://blog.google/technology/ai/google-deepmind-isomorphic-alphafold-3-ai-model/#drug-discovery. Accessed February 2025.

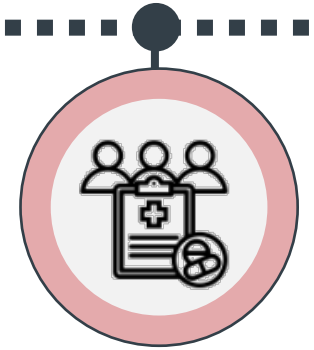
AI support opportunities in clinical trials

Study setup
- eCase report form design
- Database creation

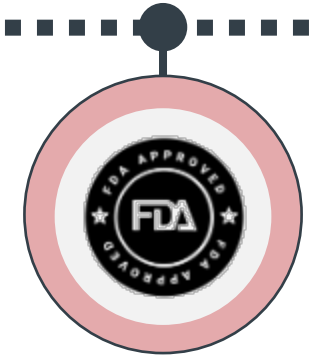


Data analysis
- Medical coding
- Interim/final analysis

Study design
- eProtocol design
- Text translation



Trial management
- Site selection
- Patient enrollment
- Risk-based monitoring



Regulatory submission
- eTrial master files
- Clinical study report automation

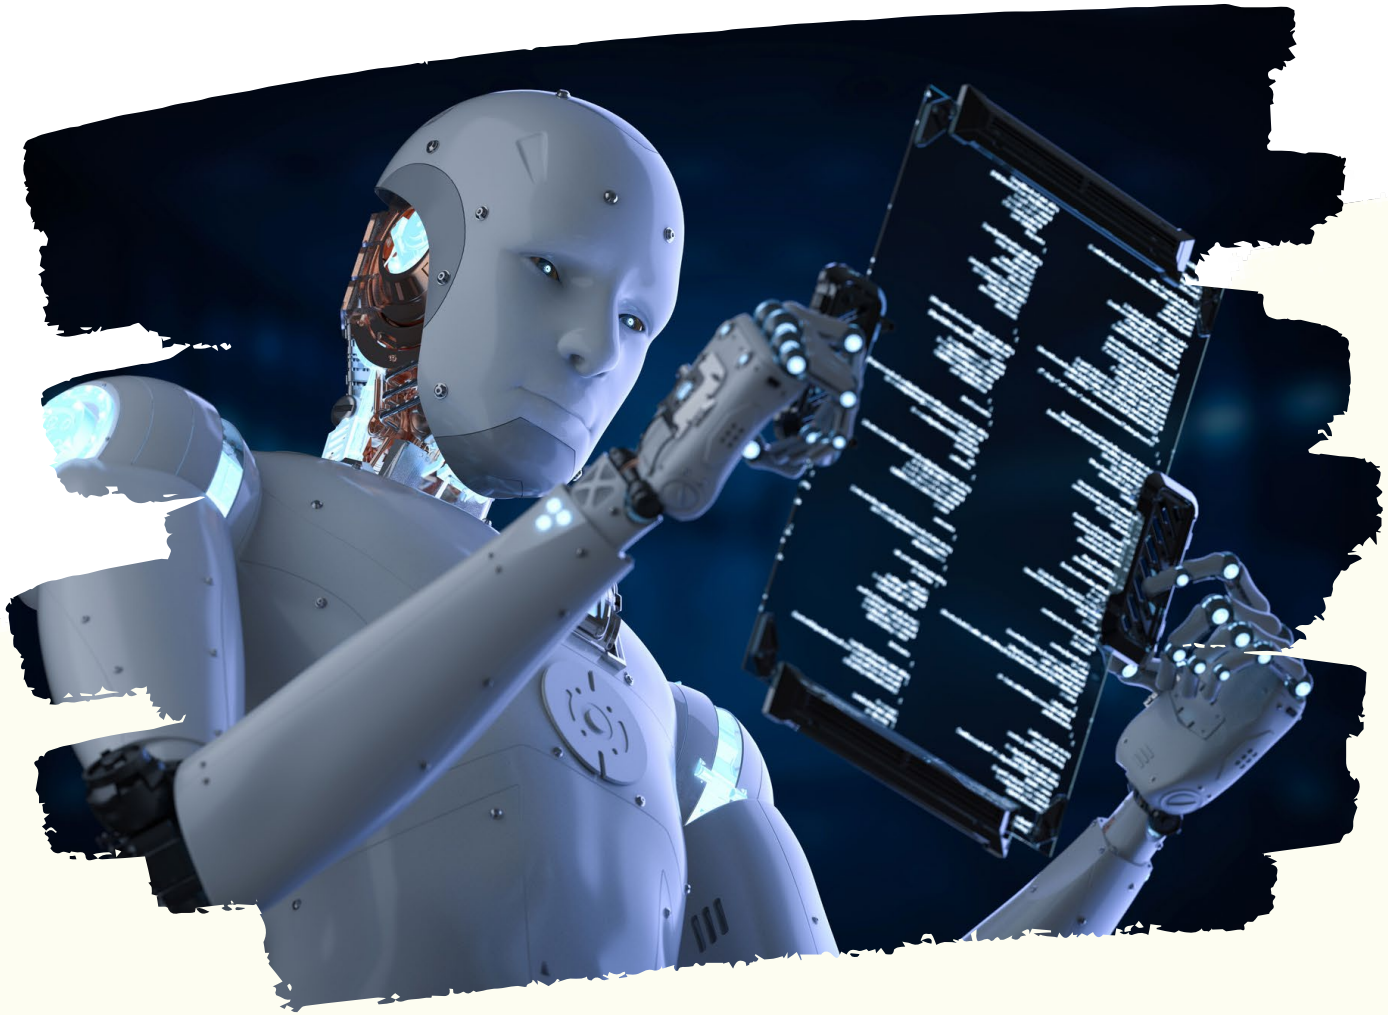
Will medicine lose its humanity?

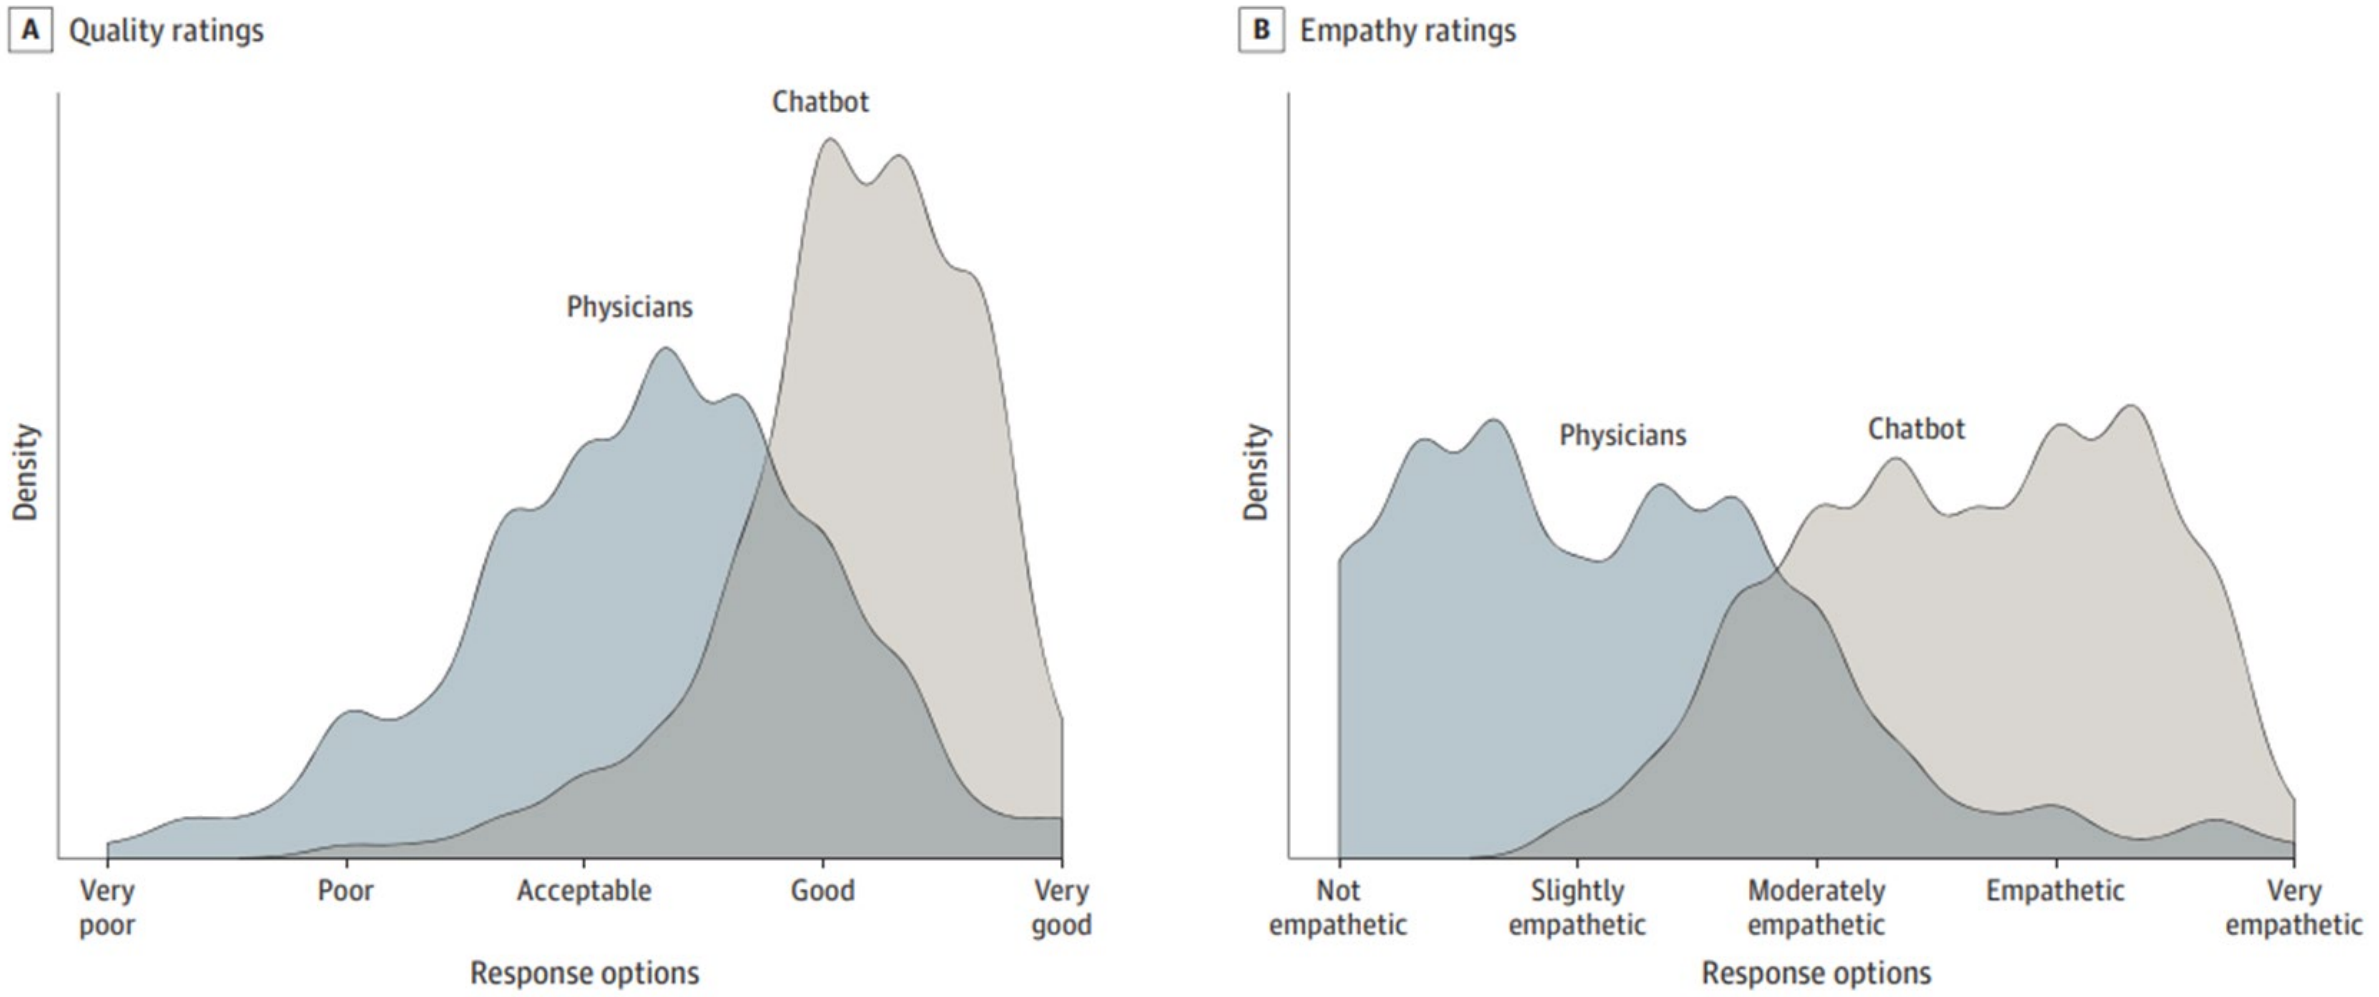


Reduced human interaction?

Loss of empathy?

Physicians compared with ChatGPT-3.5 in online patient survey

Random selection of 195 interactions in which physicians answered patient questions*

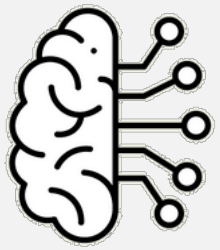


*https://www.reddit.com/r/AskDocs/

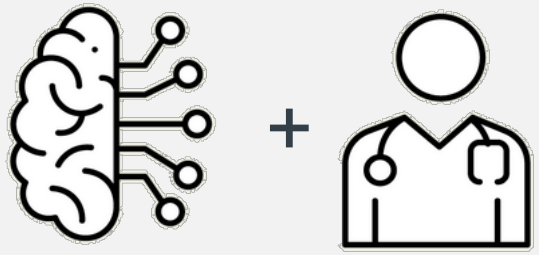
Ayers JW *et al*. *JAMA Intern Med* 2023; 183 (6): 589–596

Why hasn’t AI been able to support physicians better so far?

Median value of diagnostic judgment ability depending on the group:



92%



76%

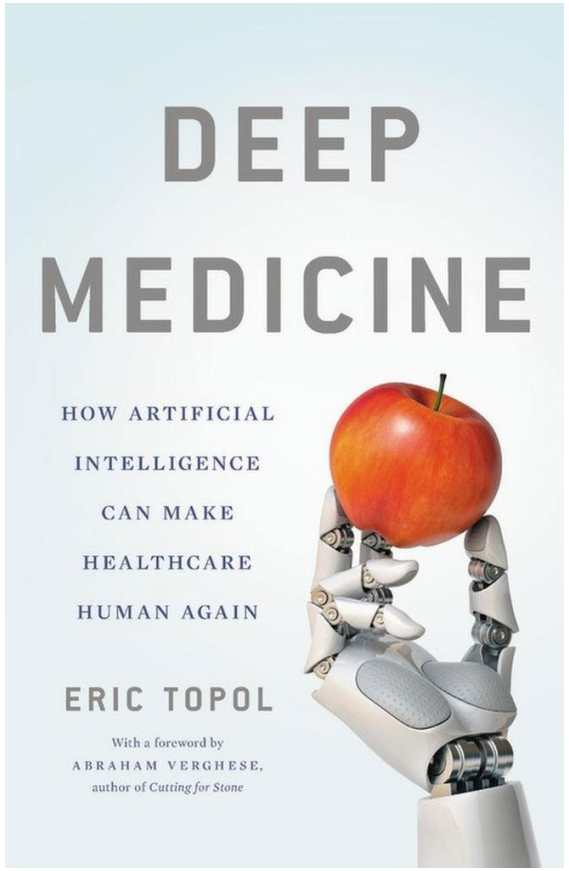
74%

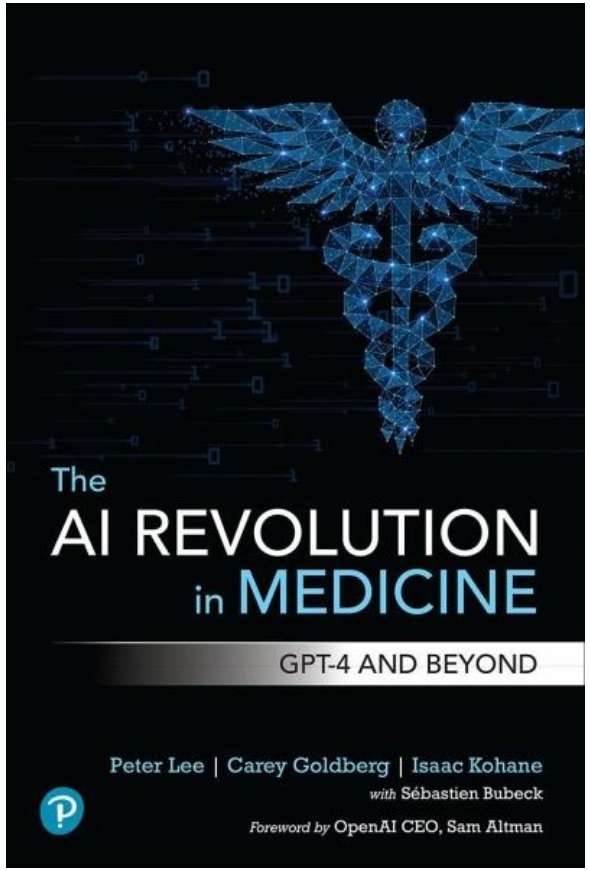
1. Physicians did not give much weight to the second opinion provided by the LLM

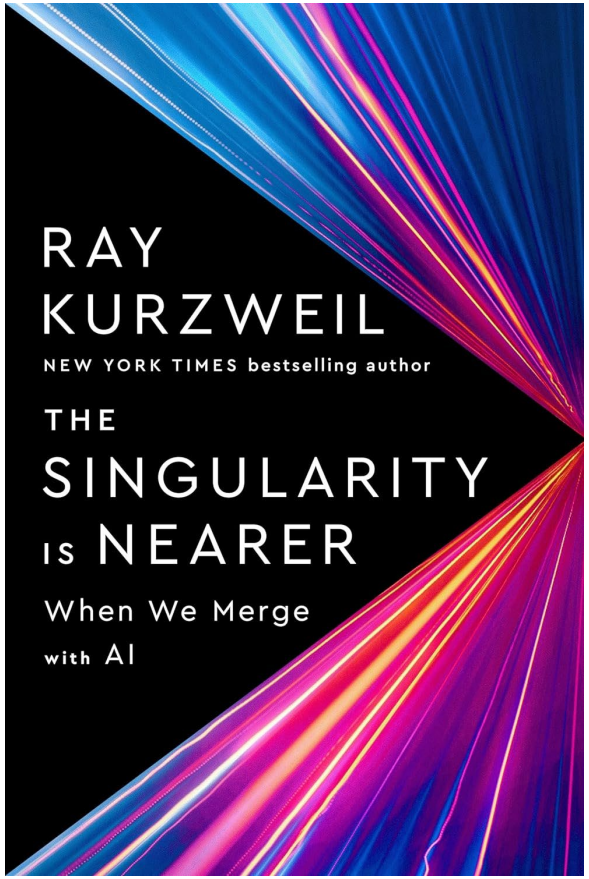
2. Physicians were not sufficiently trained to handle a chatbot/LLM

AI, artificial intelligence; LLM, large language model.
Goh E *et al*. *JAMA Netw Open* 2024; 7 (10): e2440969.

Deep medicine and the future of humans and AI







"AI will not replace physicians.
However, physicians who use AI will replace those who don't."

AI, artificial intelligence.

AI-driven diagnostics and treatment advice implementing LLMs

What's next? Artificial General Intelligence (AGI)

- **AGI – Next AI Generation:** Artificial superintelligence will continue to evolve on its own, making human control difficult or unnecessary
- **Gamechanger for technology:** AGI connects digital tools (AI as an Agent), automates processes, and revolutionizes data-intensive industries
- **Workplace in transition:** Initially inefficient, but capable of learning – AGI will quickly solve problems that we have not even recognized until now
- **Between utopia and risk:** Solutions for climate change and diseases are possible, but there is also the danger that AGI may misguide us
- **Politics drives dynamics:** Deregulation and billion-dollar contracts (see US 'Stargate') will accelerate the development of AGI and robotics – with uncertain consequences
- **Danger:** Humans – the greatest threat to the future remains humanity itself, which combines AGI, robotics, and consciousness in an 'uncontrolled' manner

What can you do?

Individual-level

1. Start discussions about how AI can be used and accepted within your medical community
   - ➢ Become familiar with regulatory guidance and consider how to address these regulations
2. Use AI to stay abreast of latest developments
   - ➢ AI tools can quickly summarize huge quantities of information

Hospital-level

1. Implement AI systems for entering and organizing patient data to free up capacity
2. Use imaging-based AI tools for initial diagnostic procedures before human input

AI, artificial intelligence.

See behind – go beyond
